

ABSTRACT

Operating mode for a communication system

A communication system has several communication devices, several communication terminals and a communication network connecting the communication terminals to the communication devices . A first address for a connection to a home communication device assigned to a specific communication terminal and a second address for a connection to an alternate communication device is stored in the communication terminals in each case. At least one terminal profile included in the terminal-relevant data is stored to which the second address can assign different communication terminals accessing the alternate communication device .
